

## Missouri Department of Natural Resources

# **Total Maximum Daily Load Information Sheet**

# **Big River and Flat River Creek**

## Waterbody Segment at a Glance:

County: St. Francois/Jefferson
Nearby Cities: Leadwood to Eureka
Length of impairment: Big River - 93 miles

Flat River Creek – 5 miles

**Pollutants:** Lead, Nonvolatile Suspended

Solids (NVSS)

Source: Old Lead Belt Abandoned

Mine Land

**Pollutant 2:** Zinc (Flat River Creek only)

**Source 2:** Elvins tailings pile

Note: Changes made in the proposed 2002 303(d)

listing (detailed on next page)

## **Description of the Problem**

### Beneficial uses of Big River and Flat River Creek:

- Livestock and Wildlife Watering
- Protection of Warm Water Aquatic Life and Human Health associated with Fish Consumption.

#### Use that is impaired

Protection of Warm Water Aquatic Life

#### Standards that apply

- Missouri Water Quality Standards for metals found in 10 CSR 20-7.031(4)(B)1 state:
   Water contaminants shall not cause the criteria in Tables A and B to be exceeded.
   Concentrations of these substances in bottom sediments or waters shall not harm benthic organisms and shall not accumulate through the food chain in harmful concentrations, nor shall state and federal maximum fish tissue levels for fish consumption be exceeded.
- The numeric standards for lead and zinc are dependent on the hardness of the water. The lead standard that applies in these waterbodies is 23 micrograms per liter ( $\mu$ /L) at a hardness of over 200. At the same hardness, the zinc standard is 433  $\mu$ /L. These are listed in Table A of the WQS.
- Standards for nonvolatile suspended solids (NVSS) can be found in the general criteria section of the WQS, 10 CSR 20-7.031(3)(A) and (C) where it states:

- Waters shall be free from substances in sufficient amounts to cause the formation of putrescent, unsightly or harmful bottom deposits or prevent full maintenance of beneficial uses.
- Waters shall be free from substances in sufficient amounts to cause unsightly color or turbidity, offensive odor or prevent full maintenance of beneficial uses.

#### **Changes in listing**

- The sediment pollutant was changed to nonvolatile suspended solids (NVSS) for both waterbodies
- Length of the zinc impairment in Flat River Creek was increased from 4.5 to 5 miles
- Elvins tailings pile was added as a source of the lead and NVSS impairments in Flat River Creek.

Flat River Creek is a tributary to Big River and their problems are intertwined. Erosion of lead tailings in the Old Lead Belt of St. Francois County in and around these waterbodies has occurred over many decades. This erosion has resulted in a large amount of sediment being deposited in pools within these streams. The sediment (or nonvolatile suspended solids) reduces the aquatic habitat quality by smothering natural substrates (materials in the streambed). Aquatic invertebrate animals (water insects and crayfish) and fish eggs are also smothered.

The impairment is being changed for the new 303(d) list from sediment to Non-Volatile Suspended Solids (NVSS). NVSS results from soil erosion or erosion of mine waste materials or stockpiles (usually silt, sand or gravel). The new listing gives a clearer picture of the specific pollutants affecting the water.

Fish and other aquatic life have accumulated elevated levels of lead in their bodies due to dissolved lead draining from the old tailings. Ninety-three miles of Big River, from Leadwood to the river's mouth, and the lower six miles of Flat River Creek presently are under a Missouri Department of Health Advisory recommending no consumption of sunfish, carp or suckers due to lead contamination of these fish. In humans, lead primarily affects the nervous system, blood cells, and processes for the metabolism of Vitamin D and calcium. Lead can affect the developing fetus during pregnancy and cause lower IQ scores, poor attention levels; hearing, speech and language problems; reading disabilities; reduced motor skills and poor hand-eye coordination. Evidence suggests that lead toxicity may occur at levels as low as 10-15 micrograms per deciliter ( $\mu$ g/dL) of blood. According to the Missouri Department of Health and Senior Services, 11% of the children in St. Francois County tested for blood lead levels actually have lead poisoning.

In addition, water draining from the Elvins chat pile in Elvins is high in dissolved zinc. During low flow periods, there is enough zinc in the drainage from the chat pile to cause toxic levels of zinc in Flat River Creek. Because compounds of zinc are generally soluble in neutral and acidic solution, zinc is readily transported in most natural waters and is one of the most mobile of the heavy metals. Hardness, dissolved oxygen, temperature and synergistic (more than the sum of the individual components) effects with other compounds all affect the toxicity of zinc to aquatic life<sup>1</sup>. Zinc is an essential nutrient to aquatic and terrestrial organisms, but in excess can be highly toxic and has the

tendency to bioaccumulate (build up in organisms) in the environment. A number of behavioral and physiological effects have been reported when test organisms have been exposed to increased zinc levels. Behavioral responses in fish include avoidance and changes in feeding rate and movement patterns. Physiological changes in fish include increased ventilation rates, frequency of coughing and a decrease in oxygen utilization.<sup>2</sup>
